

GAME-SPECIFIC FACULTY GUIDE

The Economy's Edge

A branching PPF experience built around scarcity, tradeoffs, production, and growth.

Use this guide to help students explain how their choices in Calder produced the outcome they saw. Their experience gives you a starting point for teaching the production possibilities frontier (PPF), also called the production possibilities curve (PPC).

Why This Game Exists

In designing these games, I thought about how to convey the economics without first showing a graph or asking students to do a calculation. That led me to the RPG/dungeon crawler approach: each decision changes the conditions, and the choices students make can lead to different endings.

Students often learn to label a point on a PPF efficient, inefficient, or unattainable before thinking much about the resource choices behind it. The Economy's Edge begins with those choices. Students decide what to produce and then deal with the consequences as conditions change. By the time the formal graph appears, they have an economic experience to draw on.

You can let students play before explaining the model. Once they have an outcome in front of them, ask what happened to their economy and work from their account. That is the teachable moment I wanted the game to create.

What Students Do

Students direct economic planning in the fictional country of Calder. They make six decisions, choosing among two or three available options at each stage. A run generally takes about 5–10 minutes. Allow additional time if you want to use discussion, follow-up questions, or applications in class.

They allocate fully employed workers and equipment between household goods and capital goods, reconsider that mix under pressure, respond to a delivery and job-matching disruption, and balance recovery with preparation for future production. The students' earlier choices affect later options, so they have to follow the economic story across the run.

Each choice brings a consequence and an explanation of its economic tradeoff. Four indicators track current consumption, capital production, resource utilization, and future growth, while the illustration changes with the economy's condition.

The five ending categories are continuing slack, expanded capacity, a household-oriented mix, a capital-oriented mix, and balanced recovery. With no answer score or universally best path, students need to explain what they achieved and what it cost. The six-choice history supplies the evidence behind the ending headline.

What the Game Is Really Teaching

Scarcity and opportunity cost. Calder begins with its resources fully used. More household goods require less capital production, and more capital goods require fewer household goods. Even keeping the existing mix forgoes what another allocation could provide. Ask students to identify the best alternative use they sacrificed.

Increasing opportunity cost. A stronger push toward one sector moves specialized workers and equipment into less suitable uses. The students encounter the rising cost of further concentration through the output they give up as they shift production.

Productive efficiency and preferences. Several production mixes can use available resources efficiently. On the frontier, increasing one output requires giving up some of the other. Choosing among those efficient mixes depends on what society values, so a balanced mix has no automatic claim to superiority.

Current consumption and capital formation. Equipment, infrastructure, training, and improved methods use resources now and can support later production. Households give up goods they could otherwise receive today, an opportunity cost that remains even when the investment pays off.

Four changes to keep separate

What changes in Calder	PPF interpretation
Fully used resources move between household and capital production.	Movement along a given frontier: one current output rises as the other falls.
Delivery and job-matching problems leave resources unused, without destroying them.	Production moves inside the existing frontier. Capacity remains intact.
Idle workers and equipment return to production.	Recovery toward the existing frontier. Both outputs may rise without a larger frontier.
Prepared improvements are completed and enter use.	Productive capacity expands. An outward shift permits previously unattainable combinations; choosing a mix still involves tradeoffs.

The **Future growth** indicator tracks improvements still in preparation. Producing capital goods and preparing projects today builds this pipeline; expansion occurs when completed improvements enter use. In Calder, that happens on the branch with fully used resources and sufficient preparation. The indicator can then fall as projects leave the pipeline and become usable capacity. A strong pipeline can also coexist with idle resources.

The four indicators summarize scenario conditions on simplified 0–8 scales. Their numbers describe states of the scenario, so use the written consequences to interpret them. Future growth measures preparation, with no numerical conversion to a growth rate or a third current output. The game compresses time and project completion to illustrate the mechanisms; its pace offers no forecast for a real economy.

Reading the imagery as a hidden PPF

Four regions recur in all six scene variants, making economic changes visible before students work with a conventional graph.

The balanced scene from the game. The four regions provide a visual analogy for production possibilities and changes in the economy's condition.

- **Upper left — capital goods and investment:** machinery and equipment production becomes more prominent in capital-oriented scenes.
- **Lower right — consumer goods and current consumption:** household-facing shops and activity receive greater emphasis in consumption-oriented scenes.
- **Lower left — idle or underutilized resources:** inactive workers and equipment become more evident during the slowdown and return to use during recovery. Stored materials are not an unemployment count.
- **Upper right — future improvements and expanded capacity:** training, technology, and infrastructure show preparation. The growth scene appears only when completed improvements enter use.

After play, students can connect changes in the regions to the four changes in the table. The opening text identifies the regions, and consequences explain tradeoffs. The later discussion adds a formal PPF interpretation to this visual analogy, which supplies no numerical graph coordinates.

The Educational Loop

Students can follow the instructional loop within the game. At the outcome, **What changed overall** and **Your path** help them reconstruct how their six choices produced their result. Through **Read the economics** and **Alternative decisions**, they connect those consequences to the concepts explained earlier in this guide. In **Read the frontier**, they use a schematic PPF and try three application questions in new settings. They receive explanations for correct answers and targeted feedback with a retry for errors. Finishing all three produces **Application complete**.

Experience → Consequence → Economic Explanation → Formalization → Transfer

Bringing in the PPF Graph

1. Have students choose a moment from their path and describe the economy's condition at that point.
2. Draw a bowed-out PPF with household consumer goods on the horizontal axis and capital goods on the vertical axis. Keep the diagram schematic, with no invented numerical output scales.
3. Ask students to place their chosen moment using allocation, utilization, and capacity evidence. Identify efficient and inefficient positions with reference to **Four changes to keep separate**.
4. Add a point outside the original frontier. Establish why it is currently unattainable and what would have to change to make it feasible.
5. Trace a reallocation along the curve and ask what the economy gives up. Compare a small shift with a more concentrated production mix.
6. Add the disruption and subsequent choices to the sketch. Have students distinguish recovery within existing capacity from expansion that requires a new frontier.

The built-in diagram labels efficient use of the original frontier A, slack B, and expanded capacity C. It highlights the category matching the student's outcome and explains when the dashed frontier was not reached. These are illustrative categories; the four indicators cannot supply numerical coordinates for the graph.

For a brief extension, compare Calder's disruption, which leaves productive assets intact, with a disaster that destroys factories or infrastructure. Students can contrast production inside the existing frontier with an inward shift caused by lost capacity.

Using It in Class

These are possible starting points; choose what fits your course.

Before formal instruction

Give students the link and explain how to choose and continue. Ask them to keep one decision and its consequence in mind as they play. To draw the graph together before students see the built-in version, have them pause at the outcome before **Read the frontier**.

During PPF instruction

Use a run between introducing the model and working through further examples. Collect a few outcomes for the graph procedure above, or draw on **Questions to Consider** where students need more practice.

After instruction

You might assign the game as transfer practice with a short explanation of the ending. The students' reasons for choosing a consumption–investment mix let you assess how they use the model and evidence from their path.

Independent/student review

Students can review their path and work through the follow-up independently. If you want evidence of completion, you can request a reflection or screenshot through your usual course workflow; the game has no automatic instructor report. Application attempts reset on reload, while students can still review their saved economic path.

Questions to Consider

Select any of these prompts for discussion or a short reflection.

1. What did your final economy look like, and which earlier choices most strongly explain it? Use evidence from your six-choice history.
2. Which decision had the clearest opportunity cost? Identify the gain and the best alternative output or recovery you gave up.
3. Where did your path move along a frontier, move inside it, recover toward it, or expand it? What evidence separates those changes?
4. How did the delivery and job-matching disruption change what Calder could produce versus what it actually produced? How would your analysis change if factories had been destroyed?
5. Why might the Future growth indicator fall as productive capacity increases? What does that reveal about what the indicator tracks?
6. How could two fully utilized economies choose different mixes and both be productively efficient? What would you need to know before judging one mix preferable?
7. What did households give up while capital goods and improvements were being prepared? How would you weigh that sacrifice against benefits arriving later?
8. Another country reports that both household and capital output have risen. What evidence would you ask for before deciding whether it has recovered idle capacity or expanded its productive capacity?

Common Misconceptions

- **“More capital goods mean the PPF has already shifted.”** Ask whether the improvements are still being prepared or have entered use.
- **“If both outputs rise, the economy must be growing.”** Check utilization first: recovery can raise both outputs within existing capacity.
- **“A point inside the PPF is unattainable.”** Inside points are feasible but inefficient in this model. Outside points are currently unattainable.
- **“One efficient production mix is inherently better than another.”** Ask whose priorities the mix serves. Efficiency alone cannot settle that choice.
- **“The indicators are literal output measures, percentages, or graph coordinates.”** They summarize scenario states. Ask students to support their interpretation with the written consequences.

Replay and Comparison

For an optional second run, have students record their first result, deliberately change a priority or decision, and predict the consequence and likely sacrifice before replaying.

Once they finish, ask them to compare the two histories at a similar point in the story and explain why the outcome changed or stayed similar. Their earlier choices may also have changed later options, which they should account for when evaluating the prediction.

Students can also compare with a partner. Similar endings can reveal different histories and opportunity costs, giving each student a chance to reconsider the explanation behind their prediction.

Use the game link supplied for your course; the standalone collection is in instructor preview at the time of this guide. General teaching and implementation resources are available at [Mastery Quests Faculty Resources](#).
