Average Costs: AFC, AVC & ATC

THE CORE IDEA

Average fixed cost, average variable cost, and average total cost express costs per unit of output. Average total cost equals average fixed cost plus average variable cost. Average fixed cost falls as output spreads the same fixed cost across more units, while average variable cost changes with the productivity and price of variable inputs.

HOW TO RECOGNIZE IT

- Divide fixed cost by output for average fixed cost and variable cost by output for average variable cost.
- Average total cost equals average fixed cost plus average variable cost.
- Average fixed cost falls continuously as output spreads the same fixed cost across more units.
- Use per-unit measures only when output is positive.

WATCH OUT

A common mistake is to misuse average cost formula. $AVC = \$300/20 = \15 ; $AFC = \$5$; $ATC = \$20$. $TVC = \$1,000$; $AVC = \$20$, $AFC = \$8$, and $ATC = \$28$.

WORKED EXAMPLE: READING AVERAGE-COST CURVES

At 400 units, the graph shows average cost of \$20 and average variable cost of \$12. Because $AC = AVC + AFC$, average fixed cost is $\$20 - \$12 = \$8$ per unit. The gap between AC and AVC is therefore the firm's average fixed cost.

CHECK YOURSELF

Cost schedule 2: At $Q=29$, Ironwood Furniture has $AVC=\$13.97$ and $ATC=\$24.31$. What fixed-cost conclusion follows?
