LRAC, Economies & Diseconomies of Scale

THE CORE IDEA

Long-run average cost shows the lowest attainable cost per unit when every input and plant size can vary. Scale can make specialized tasks and equipment economical, lowering LRAC over a range. Diminishing marginal product is a short-run concept; diseconomies concern scale when all inputs can vary. Falling long-run average cost as output expands is economies of scale.

HOW TO RECOGNIZE IT

- Diminishing marginal product is a short-run concept; diseconomies concern scale when all inputs can vary.
- A learner reads a downward-sloping LRAC segment as diseconomies of scale.
- The concepts apply to different horizons and input changes.
- A very large firm becomes harder to coordinate.

WATCH OUT

Do not confuse scale and diminishing returns. Diminishing marginal product is a short-run concept; diseconomies concern scale when all inputs can vary.

WORKED EXAMPLE: READING LONG-RUN AVERAGE COST

The LRAC curve falls from about \$20 at 30 units to its minimum of about \$12 at 60 units, showing economies of scale. It then rises back toward \$20 by 90 units, showing diseconomies of scale. The cost-minimizing scale is approximately 60 units.

CHECK YOURSELF

The graph gives roughly the same LRAC at $Q=30$ and $Q=90$. Which statement distinguishes those two positions?
