Monopoly Welfare, Efficiency & Competitive Comparison

THE CORE IDEA

Compared with competition, monopoly usually restricts output, raises price, transfers surplus, and creates deadweight loss. Transfers remain in total surplus; unrealized trades do not. The omitted units would generate positive gains from trade. Market power generally leads the monopolist to restrict output and charge a higher price than the competitive benchmark.

HOW TO RECOGNIZE IT

- Compare monopoly output and price with the competitive benchmark where price equals marginal cost.
- Monopoly normally produces less and charges more than a competitive market.
- Separate the transfer of surplus to the monopolist from surplus lost through reduced output.
- Deadweight loss is the value of trades between monopoly output and the efficient quantity that no longer occur.

WATCH OUT

A common mistake is to reverse monopoly competitive comparison. Market power generally leads the monopolist to restrict output and charge a higher price than the competitive benchmark.

WORKED EXAMPLE: IDENTIFYING MONOPOLY DEADWEIGHT LOSS

The unregulated monopoly chooses about 45 units where $MR = MC$ and charges the demand price of about \$47. The efficient outcome occurs where demand meets MC: 90 units at \$20. Monopoly therefore restricts output and raises price, leaving mutually beneficial units between 45 and 90 unproduced.

CHECK YOURSELF

Which part of lost consumer surplus is deadweight loss?
