Externalities

+

THE CORE IDEA

An externality is a cost or benefit imposed on someone outside a transaction. Negative externalities make private decision makers ignore part of social cost; positive externalities make them ignore part of social benefit. Efficiency uses all marginal social costs and benefits.

?

HOW TO RECOGNIZE IT

- Ask whether the spillover is a cost or benefit and whether it comes from production or consumption.
- Negative: $MSC > MPC$ or $MPB > MSB$, so the market quantity is too high.
- Positive: $MSB > MPB$ or $MPC > MSC$, so the market quantity is too low.
- Corrective taxes, subsidies, permits, regulation, or bargaining can internalize the spillover.

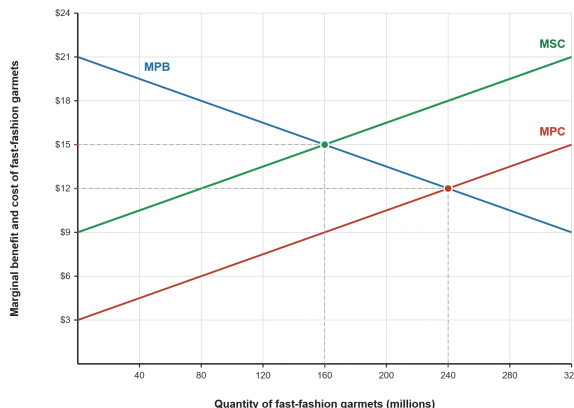

!

WATCH OUT

Do not label every harmful outcome an externality. A spillover must affect a third party and be missing from the market price.

#

WORKED EXAMPLE: NEGATIVE PRODUCTION EXTERNALITY

Fast-fashion production creates a \$6 external cost per garment, so MSC lies \$6 above MPC. The market produces 240 million garments where $MPB = MPC$ at \$12. Efficiency occurs at 160 million garments where $MPB = MSC$ at \$15, eliminating 80 million units of overproduction. A \$6 corrective tax aligns private and social marginal cost.

?

CHECK YOURSELF

If MSB lies above MPB, is the unregulated market quantity too high or too low?
